Unit 6: Introduction to linear regression

2. Outliers and inference for regression

Sta 104 - Summer 2018, Term 2

Uncertainty of predictions

- ► Regression models are useful for making predictions for new observations not include in the original dataset.
- ▶ If the model is good, the predictions should be close to the true value of the response variable for this observation, however it may not be exact, i.e. \hat{y} might be different than y.
- ▶ With any prediction we can (and should) also report a measure of uncertainty of the prediction.

- ▶ Lab 7 is due today at 12:45 pm
- ► Readiness Assessment 7 is Friday in class
- ▶ Problem Set 6 is due Saturday 11:55 pm
- Performance Assessment 6 is due Saturday 11:55 pm
- ▶ Lab 8 is due Monday at 12:45 pm
- Project Slides are due Wednesday 11:55 pm
- ▶ Problem Set 7 is due Thursday 11:55 pm
- Performance Assessment is due Thursday 11:55 pm
- Project Files are due Thursday 11:55 pm
- ▶ Lab 9 is due Thursday 11:55 pm

Prediction intervals for specific predicted values

A prediction interval for y for a given x^* is

$$\hat{y} \pm t_{n-2}^{\star} s_{\chi} \sqrt{1 + \frac{1}{n} + \frac{(x^{\star} - \bar{x})^2}{(n-1)s_{\chi}^2}}$$

where S is the standard deviation of the residuals, and X^* is a new observation.

- ▶ Interpretation: We are XX% confident that \hat{y} for given x^* is within this interval.
- ▶ The width of the prediction interval for \hat{y} increases as
 - X[★] moves away from the center
 - S (the variability of residuals), i.e. the scatter, increases
- ▶ Prediction level: If we repeat the study of obtaining a regression data set many times, each time forming a XX% prediction interval at X^{*}, and wait to see what the future value of *y* is at X^{*}, then roughly XX% of the prediction intervals will contain the corresponding actual value of *y*.

By hand:

Don't worry about it...

In R:

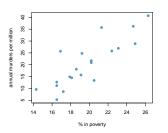

```
# predict
predict(m_mur_pov, newdata, interval = "prediction", level = 0.95)
```

```
fit lwr upr
1 21.28663 9.418327 33.15493
```

We are 95% confident that the annual murders per million for a county with 20% poverty rate is between 9.52 and 33.15.

Clicker question

 R^2 for the regression model for predicting annual murders per million based on percentage living in poverty is roughly 71%. Which of the following is the correct interpretation of this value?

- (a) 71% of the variability in percentage living in poverty is explained by the model.
- **(b)** 84% of the variability in the murder rates is explained by the model, i.e. percentage living in poverty.
- 71% of the variability in the murder rates is explained by the model, i.e. percentage living in poverty.
- 6 71% of the time percentage living in poverty predicts murder rates accurately.

- \triangleright R^2 : percentage of variability in y explained by the model.
- ► For single predictor regression: R^2 is the square of the correlation coefficient, R.

```
murder %>%
summarise(r_sq = cor(annual_murders_per_mil, perc_pov)^2)

r_sq
1 0.7052275
```

For all regression: $R^2 = \frac{SS_{reg}}{SS_{tot}}$

anova(m_mur_pov)

Analysis of Variance Table

Response: annual_murders_per_mil
 Df Sum Sq Mean Sq F value Pr(>F)
 perc_pov 1 1308.34 1308.34 43.064 3.638e-06 ***
Residuals 18 546.86 30.38

$$\textit{R}^2 = \frac{\textit{explained variability}}{\textit{total variability}} = \frac{\textit{SS}_{\textit{reg}}}{\textit{SS}_{\textit{tot}}} = \frac{1308.34}{1308.34 + 546.86} = \frac{1308.34}{1855.2} \approx 0.7$$

Inference for regression uses the *t*-distribution

- ▶ Use a T distribution for inference on the slope, with degrees of freedom n-2
 - Degrees of freedom for the slope(s) in regression is df = n k 1 where k is the number of slopes being estimated in the model.
- ▶ Hypothesis testing for a slope: $H_0: \beta_1 = 0$; $H_A: \beta_1 \neq 0$
 - $T_{n-2} = \frac{b_1 0}{SE_{b_1}}$
 - p-value = P(observing a slope at least as different from 0 as the one observed if in fact there is no relationship between X and Y
- ► Confidence intervals for a slope:

$$-b_1 \pm T_{n-2}^{\star} SE_{b_1}$$

- In R:

 $confint(m_mur_pov, level = 0.95)$

```
2.5 % 97.5 %
(Intercept) -46.265631 -13.536694
perc_pov 1.740003 3.378776
```

5

Important regardless of doing inference

▶ Linearity → randomly scattered residuals around 0 in the residuals plot
 - important regardless of doing inference

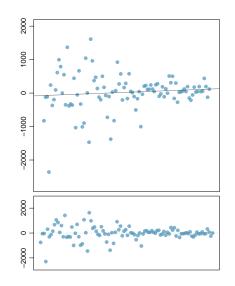

Important for inference

- Nearly normally distributed residuals → histogram or normal probability plot of residuals
- ► Constant variability of residuals (*homoscedasticity*) → no fan shape in the residuals plot
- ► Independence of residuals (and hence observations) → depends on data collection method, often violated for time-series data

Clicker question

What condition is this linear model obviously and definitely violating?

- a Linear relationship
- (b) Non-normal residuals
- © Constant variability
- d Independence of observations

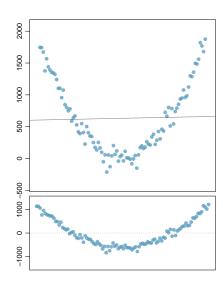

Checking conditions

8

Clicker question

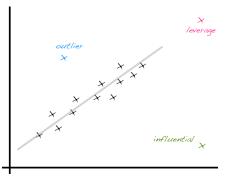

What condition is this linear model obviously and definitely violating?

- a Linear relationship
- Non-normal residuals
- Constant variability
- d Independence of observations

Type of outlier determines how it should be handled

- ► Leverage point is away from the cloud of points horizontally, does not necessarily change the slope
- ► Influential point changes the slope (most likely also has high leverage) run the regression with and without that point to determine

- Outlier is an unusual point without these special characteristics (this one likely affects the intercept only)
- ▶ If clusters (groups of points) are apparent in the data, it might be worthwhile to model the groups separately.

9

Application exercise: 6.2 Linear regression

See course website for details

Summary of main ideas

- 1. Predicted values also have uncertainty around them
- 2. R^2 assesses model fit higher the better
- 3. Inference for regression uses the t-distribution
- 4. Conditions for regression
- 5. Type of outlier determines how it should be handled
